Louis Merlin

Abstract

The abstract serves as an executive summary of your project. Your abstract should cover at least the following topics, 1-2 sentences for each: what area you are in, the problem you focus on, why existing work is insufficient, what the high-level intuition of your work is, maybe a neat design or implementation decision, and key results of your evaluation.

Chapter 1

Introduction

Work on C++ began in 1979, as a "C with classes" [19]. Since then, the language has grown in popularity, and even surpassed C itself [17]. Examples of well-known C++ projects include the zoom [4] conferencing software, the gold linker [20] or [TODO: find another "well-known" example]. Nevertheless, reverse-engineering efforts have been focused towards C binaries, because analysis methods found this way will often work on C++ binaries too.

This has meant reverse engineering tools like ghidra [12], IDA Pro [15] or Binary Ninja [1] have treated non-C binaries as second-class citizen. These tools will often show C++ specific features as passing comments, failing to show the real implications of a try/catch block or a polymorphic class.

The blame can mostly be put on the complexity of C++ when compared to C. Whereas C translates quite naturally to assembly, abstractions specific to C++ require more work and complexity to be translated to asm. This also leads to important information being lost from C++ source code to binary, but also certain information remaining.

The recent RetroWrite [7] project by the HexHive lab is a static rewriting tool for x86_64 position-independent binaries. It enables the instrumentation of projects when we do not have access to the source code. This can include a legacy project, a closed-source product or even malware.

In this thesis we would like to present the **dis-cover** [10] static analysis tool, as well as improvements made to RetroWrite to support C++ binaries.

The dis-cover tool is able to extract information from a C++ binary, and re-inject it as debug information using the DWARF format into the binary. This enables other debugging tools to see and display this information.

[IF WE SUCCEEDED] In this thesis we would like to show how we brought C++ support to RetroWrite, and what research opportunities this will create.

[IF WE FAILED] In this thesis we will detail how we tried to bring C++ support to RetroWrite, and what remains to be done for the implementation to work.

Chapter 2

Background

2.1 C++ and polymorphism

The C++ programming language implements polymorphism. This feature enables complex code logic that can comply with external business logic for example. Polymorphic classes are defined by having at least one virtual method, which is inheritable and overridable. With this polymorphism comes type conversion, and more interestingly for us the **dynamic_cast** [5] expression. Dynamic casting is a safe kind of type conversion. It only will successfully cast if the value is of the referenced type or a base type of that type. In order to achieve that, the system must have some kind of information about the object's data type at runtime.

This is where Run-Time Type Information (**RTTI**) comes into the picture. The system will use this RTTI to infer type inheritance for dynamic casting. We will now go into implementation details of RTTIs and VTables, which point to them.

To make RTTIs appear in your C++ binary, you will to define classes that inherit from each other, as well as at least one virtual method in one of these classes. Figure 2.1 shows an example of such classes.

```
class Animal {  
public:  
    virtual void speak() {}  
};  
  
class Dog {  
public:  
    virtual void speak() { cout << "Woof" << endl; }  
}
```

Figure 2.1: Polymorphic classes in C++

For RTTIs to appear in your C++ binary, you will also need to instantiate these classes, and have some runtime logic to make the binary non-deterministic [this not the right word I think, I mean to say that the binary depends on some input for its class-instantiation logic]. For example, a conditional dynamic cast between the two classes we defined in Figure 2.1. If you do not do these things, the class logic will be abstracted away by the compiler for optimization reasons.

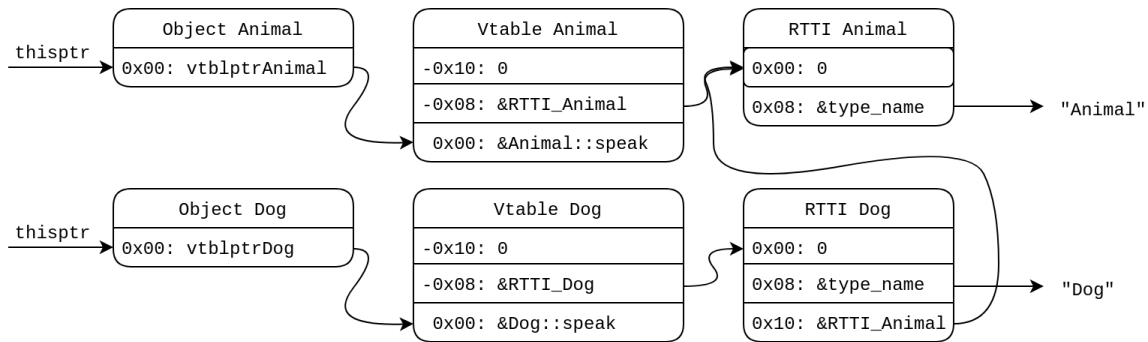

Figure 2.2: Overview of an example of VTables and RTTI in memory

The structure of VTables and RTTIs is detailed in Figure 2.2. All of this is defined in the Itanium C++ ABI [8]. An instance of a virtual class **Animal** will contain the **vtblptrAnimal**, a pointer to the virtual table (**VTable**) for the **Animal** class. This VTable will contain pointers to the virtual methods of the class, which are inherited and thus do not have to be duplicated for each class, they are simply pointed to. The first value preceding the VTable is a pointer to the RTTI of the class. The process finds out the class inheritance of a class instance by following this pointer.

The RTTI itself is composed of an offset (used for complex class inheritance structures) as well as a pointer to the type name (this type name is not removed by simple stripping of the binary, like with **objcopy -strip-all**). This name is mangled using C++ mangling, and can trivially be demangled. This name is what we use to uniquely identify a class in a project (and make sure we have no duplicates). The next values of the RTTI are pointers to the RTTIs of the parent classes. See Figure 2.2 for an example, with the **Dog** RTTI containing a pointer to the **Animal** RTTI.

2.2 DWARF debugging standard

DWARF is the debugging standard used widely in conjunction with executable ELF files. It is often included in these ELF files in the **.debug_info** section (and other related sections). This debug information is made up of Debugging Information Entries (**DIEs**). These entries can contain information about variable names, method definitions, the compilation process, or more importantly for us, class names and class inheritance.

2.3 RetroWrite

Chapter 3

Design

Introduce and discuss the design decisions that you made during this project. Highlight why individual decisions are important and/or necessary. Discuss how the design fits together.

This section is usually 5-10 pages.

Class recovery from compiled C++ binaries has been done multiple ways before: there are plugins for popular debugging tools, like `ida_gcc_rtti` [11] for IDA Pro, or Ghidra-Cpp-Class-Analyzer [18] for Ghidra; there are academic projects such as MARX [14] that rely on heuristics around VTables to find classes and inheritance information. The MARX project can recover classes when no RTTI is present (in the Chrome project for example, where the **fno-rtti** compilation flag is used), but not with 100% accuracy.

For this project we decided to focus on RTTIs which, as mentioned in the Background chapter, are available for a class hierarchy tree when there is at least one virtual method implemented by one of the classes. We decided to test if RTTIs occurred often in the wild : we proceed to download every Debian package that listed C++ as a dependency (get the list with **apt-cache rdepends libgcc1** on a debian machine). Out of around 80'000 packages, 5827 of them list C++ as a dependency. Out of those, we were able to extract classes from 3194 (54%). We will share more details about this experiment in the Evaluation chapter.

We also considered extracting information about exceptions, which is another big feature that differentiates C++ from C. We decided not to focus on this feature, as it did not seem to bring as much to the project considering the evaluated development time. We did have to study and work with exceptions and exception handling frames for the augmentation of RetroWrite (see the end of the Implementation chapter).

Next comes the question : what should we do with all of this information ? What would be the most useful format to output the data in ? This is where DWARF [3] comes in the picture. DWARF is the debugging standard for programs. It is mostly used by developers trying to understand

where their implementation fails, and by reverse engineers to get a better understanding of how a program was conceived (although DWARF information is usually stripped from proprietary software). This kind of debug data is mostly found in C and C++ projects. By having DWARF data as an output, the information would become readable by most modern reversing tools.

There is a current push for DWARF to become the lingua franca for reverse engineering tools, lead by researchers like Dr. Sergey Bratus [6] from DARPA. He has published a paper in 2011 where he was able to exploit certain features of DWARF to control program execution : Exploiting the hard-working DWARF [13].

With dis-cover, we are able to inject information in the debug and symbol sections of the binary, creating a new ELF file with all of this useful info included. We will go more into the implementation details in the next chapter.

Another focus of this project was the augmentation of RetroWrite for C++ capabilities. Today, RetroWrite supports the reversing of x86_64 position-independent binaries. There was also work to augment RetroWrite to support kernel code [16] and arm_64 [2]. We aimed to add C++ capabilities for x86_64 binaries only, as it seems like the biggest target.

Another potential use of the class information is to implement defenses around type confusion, working with the findings from the HexType [9] paper. We decided not to focus on this for our project, as it would have been out of the scope of a 6-months master thesis.

Chapter 4

Implementation

The implementation covers some of the implementation details of your project. This is not intended to be a low level description of every line of code that you wrote but covers the implementation aspects of the projects.

This section is usually 3-5 pages.

Chapter 5

Evaluation

In the evaluation you convince the reader that your design works as intended. Describe the evaluation setup, the designed experiments, and how the experiments showcase the individual points you want to prove.

This section is usually 5-10 pages.

As we have shown before, out of the 5827 debian packages that list C++ as a dependency, we were able to extract classes from 3194 (54%). The total number of classes we found is 960'188, with 39% of them unique across all packages (unique name in unique tree).

Chapter 6

Related Work

The related work section covers closely related work. Here you can highlight the related work, how it solved the problem, and why it solved a different problem. Do not play down the importance of related work, all of these systems have been published and evaluated! Say what is different and how you overcome some of the weaknesses of related work by discussing the trade-offs. Stay positive!

This section is usually 3-5 pages.

Chapter 7

Conclusion

In the conclusion you repeat the main result and finalize the discussion of your project. Mention the core results and why as well as how your system advances the status quo.
